AML Lab Sessional 1 Jupyter Notebook

1. VS Code is a MUST

1. You should code in VS Code. Google Colab not allowed

2. Pre-requisites for lab in VS Code

1. Install PDF export support https://saturncloud.io/blog/how-to-export-jupyter-notebook-by-vscode-in-pdf-format/

3. At the end, export your notebook as html and ipynb

1. Open VS Code command palette Shift + Ctrl + P
2. Type "Export Jupyter Notebook" in the search bar and select "Export Jupyter Notebook to html"
3. Upload your html AND ipynb here: https://tinyurl.com/y9ptbej2 (In the prompt, put your name correctly else your submission will be rejected)

4. Lab Sessional Summary

1. A code template is given to you in lab sesional in this jupyter notebook
2. The template will follow a linear sequence of TODOs appropriately labelled with question marks
3. You will have to fill the TODO question marks to compile those notebook cells and proceed to next cells
4. You can think of the linear sequence of TODOs as a guided thought process.
5. Sessional is open book. Google, github, browse product documentation ChatGPT - Do anything you want, except copying others. No discussing among yourselves (Sending questions to your seniors and seeking answers is prohibited). If you are caught carrying out these illegal activities, you will be reported for immediate action.
6. You CANNOT replace the TODO code template with some other code copied from stack overflow, ChatGPT etc. All your browsing and search should give you insights into finally how you can fit that into the framework I provide for the thought process of solving the problem. You will have to mandatorily fill the question marks and proceed with the lab problem.

In [ ]:
```
import numpy as np
import pandas as pd
import sklearn as sk

import matplotlib.pyplot as plt
import seaborn as sns
%matplotlib inline

import warnings
warnings.filterwarnings("ignore")
```

In [ ]:
```
sk.__version__
```

Out[ ]:
```
'1.3.0'
```

Problem Definition

You are provided with diabetes dataset. Your task is:

1. Part 1: To perform EDA and prediction without pipeline
2. Part 2: To move EDA and kNN prediction into a pipeline
3. Part 3: To combine the pipeline and gridsearch to get best K and weights hyperparameters
4. Part 4: Save the model as json file, load & use it to do prediction. This part is optional and will be used to accumulate bonus points as a buffer for the semester lab exam if there is any shortfall

Part 1 - Perform EDA and prediction without pipeline

Deciding on Imputation

1. Now you should decide which imputation to use - whether SimpleImputer or IterativeImputer
2. Instead of following MCAR/MAR path to decide on SimpleImputer or IterativeImputer, you will take a simple alternative
3. Use IterativeImputer if a large number of rows have Nan for a column
4. Use SimpleImputer if the number of Nans is very small

Iterative Imputer uses all non null features of the dataset to impute. To apply Iteratative Imputer on the two columns identified above, you should have all other features combined into the dataframe or numpy nmatrix first.

You should do the following for that

1. Remove the columns of the dataframe that were subjected to mean imputation
2. Convert the remaining dataframe into numpy matrix
3. Combine the above numpy matrix with mean imputed columns earlier. The "combining" two matrices is achieved by concatenating those two numpy matrices - by using an appropriate numpy stacking function
4. The stacked numpy matrix is then used for iterative imputation

In [ ]:
```
# TODO: 21 Remove the columns of X_train dataframe that were already subjected to m
# Hold on to the rest as a Numpy matrix
X_train_set_aside = X_train.drop(["Glucose", "BloodPressure", "BMI"], axis=1).to_nu
X_train_set_aside
```

0.7688172043010753
```

Part 2: Data processing and prediction using a pipeline

In [ ]:
```
# TODO: 28 Repeat activities that need to be done outside pipeline
# Reading csv, dropping duplicates & other steps that you might have performed - bu

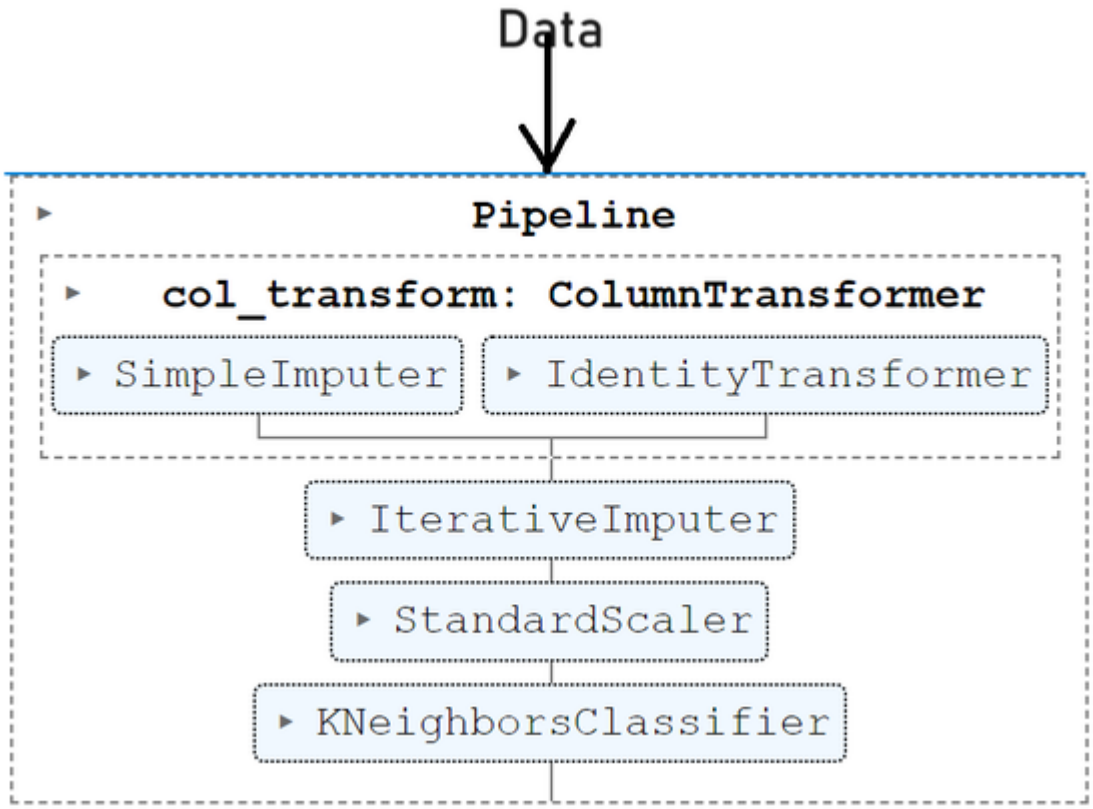
df = pd.read_csv("d2.csv")
df.drop_duplicates(inplace=True)
#Add other code for dropping duplicates etc
```

In [ ]:
```
# TODO: 29 Split the data into X and y. Then do train test split here

y = df.pop("Outcome")
X = df

X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.25, random_st
```

Design a pipeline that looks like following:



1. SimpleImputer performs mean imputation only on the relevant columns
2. IdentityTransformer (whose code is given below) is a custom sklearn transformer that performs no operation on the input data. Input data is passed through as is
3. The two are wrapped within a ColumnTransformer
4. This is followed by sequential execution of IterativeImputer, StandaScaler and the KNN based clasifier

In [ ]:
```
# This is a No-op transformer. Use this as is
from sklearn.base import BaseEstimator, TransformerMixin

class IdentityTransformer(BaseEstimator, TransformerMixin):
    def __init__(self):
        pass

    def fit(self, X, y=None):
        return self

    def transform(self, X, y=None):
        return X*1
```

Look at the columns of the dataframe and decide which ones need to go to SimpleImputer and which ones should go to IdentityTransformer

In [ ]:
```
df.columns
```

Out[ ]:
```
Index(['Pregnancies', 'Glucose', 'BloodPressure', 'SkinThickness', 'Insulin',
       'BMI', 'DiabetesPedigreeFunction', 'Age'],
      dtype='object')
```
